How Can I Live With Heart Failure?

About 6 million Americans are currently living with heart failure. In fact, it’s one of the most common reasons people 65 and older go into the hospital.

Heart failure is a long-term (chronic) condition, but it can be treated. Getting good medical care and following your treatment plan will help you have the best quality of life.

You can help by taking your medications as prescribed and following your eating and exercise plans.

What lifestyle changes will I need to make?

It’s important to monitor your symptoms and make lifestyle changes to help you manage your heart failure.

You’ll need to:

• Follow a heart-healthy diet that’s low in saturated fat, sodium and added sugars and avoid trans fats.
• Limit your sodium intake to 1,500 milligrams a day or less.
• Limit your fluid intake.
• Monitor your blood pressure and know your numbers. Your health care professional will recommend the blood pressure level and treatment plan for you.
• Monitor your heart rate.
• Monitor your weight daily and watch for sudden weight gain.
• Manage anemia and iron deficiency if you have been diagnosed with it.
• Take steps to improve the quality of your sleep by:
  – Raising the head of the bed or using a wedge to sleep at an incline.
  – Treating sleep apnea by using a continuous positive airway pressure (CPAP) machine.
• Changing the time you take your diuretics to reduce bathroom trips during the night.
• Get regular, moderate-intensity physical activity. Talk to your health care professional about an exercise plan that will work for you.

What medicine might I take?

The goal of heart failure treatment is to help you live a longer, better-quality life. Treating the causes of heart failure with medication can lessen tiredness (fatigue), shortness of breath and swelling. It also helps improve your energy level so you can be physically active.

Here are some examples of medicines that may be prescribed:

1. **Angiotensin converting enzyme (ACE) inhibitors** and **ARBs** (angiotensin receptor blockers) — lower blood pressure and decrease the heart’s workload.
2. **Angiotensin-receptor neprilysin inhibitors (ARNIs)** — improve artery opening and blood flow, reduce sodium (salt) retention and decrease strain on the heart.
3. **Aldosterone antagonists and diuretics** — help your body get rid of extra fluid and sodium.

(continued)
4. Beta-blockers and I, channel blockers (or inhibitors) — slow the heart rate and reduce the heart’s work load.
5. Digoxin — helps your heart pump better.
6. Vasodilators — lower blood pressure by relaxing blood vessels and allowing them to open (dilate).
7. Sodium-glucose cotransporter-2 (SGLT-2) inhibitors — improve blood glucose control and decrease body weight and blood pressure.

What else can I do?
Cardiac rehabilitation can be an important step in the journey to recovery and wellness for people with heart failure. Cardiac rehab is a medically supervised program that includes exercise training, education on heart-healthy living and often counseling to reduce stress. For many people with heart failure, cardiac rehab plays a critical role in improving the quality and length of life.

What should I watch out for?
Call your health care professional right away if you:
- Gain 3 or more pounds in a day.
- See swelling in your feet, ankles or other parts of your body.
- Are having a hard time breathing.
- Can’t do what you could do the day before.
- Get a fever.
- Have chest pain.
Other ways to tell that your heart might not be working the way it should include:
- Coughing up pinkish, blood-tinged mucus.
- Confusion, difficulty thinking, dizziness or lightheadedness.
- Changes in your eating habits or appetite.

My health care professional’s advice
