Acute Dizziness: Is It a Stroke?

Gordon Kelley MD
November 2017
• No Disclosures
Dizziness

- Occurs in nearly $\frac{3}{4}$ of cerebellar strokes
- 4 categories in classic teaching*:
  - Vertigo
  - Presyncope
  - Imbalance
  - Non-specific dizziness
- Patients can’t tell the difference! Timing and triggers may be more useful
  - Abrupt onset more typical of stroke
  - Acute vestibular syndrome intolerant of head movement

*Drachman and Hart, 1972
Acute Vestibular Syndrome

- Acute dizziness
- Nausea & vomiting
- Unsteady gait
- Nystagmus
- Intolerance to head motion
Labyrinthitis

• aka vestibular neuronitis

• Pathology localizes to the inner ear or 8th cranial nerve

• True cause usually unknown; presumed viral similar to Bell’s palsy

• Outcome usually good (better with course of steroids)
Vertebrobasilar Strokes

• Symptoms and signs are undervalued in NIHSS and F/A/S

• Clinical trials of thrombolytics have underrepresented or excluded these patients
Acute Vestibular Syndrome

- In ER, cause is about
- 75% Labyrinthitis
- 25% Stroke
Ataxia

- Central lesions without ataxia are rare: AVS without ataxia is usually peripheral
- Grade 3 ataxia has 66.7% sensitivity and 100% specificity

Carmona et al Fron Neurol. 2016;7: 125
All patients with Grade 3 ataxia had Babinski’s asynergia sign first described in 2013.
Allows evaluation in bed w/o testing gait.
HINTS Exam

• A 3 part bedside exam taking less than 5 minutes is more sensitive than MRI in identifying acute stroke (sensitivity 98%, specificity 95% for HINTS vs 80% & 97% for MRI DWI)

• After a directed history and exam including NIHSS and observing gait, the HINTS exam involves
  – the head impulse test
  – observation of nystagmus
  – Looking for skew deviation of the eyes

ACUTE DIZZINESS

ACCOMPANYING NEUROLOGICAL SYMPTOMS

Diplopia, dysarthria, weakness, numbness, ataxia, acute headache do NIHSS; walk patient also consider systemic factors: e.g. a.fib., hypertension, hyponatremia

1. HORIZONTAL HEAD IMPULSE

2. Look for NYSTAGMUS

Direction Changing and/or Rotatory/vertical

unidirectional

positive

no

3. SKEW DEVIATION

positive

negative

yes

yes

STROKE (Central)

VESTIBULAR NEURONITIS (Peripheral)

ALL 3 HINTS tests should be present for Dx of Vestibular Neuronitis. ANY 1 HINTS test present could indicate Stroke

* Peripheral nystagmus may suppress with fixation: -look for nystagmus with ophthalmoscope or look for eye movements with eyelids closed (both suppress fixation)

If no nystagmus, negative head impulse or skew, do Dix-Hallpike to look for BPPV.

Gordon Kelley MD   April 2017
Horizontal Head Impulse Test

- Have the patient fixate on your nose
- Passively turn their head 15 degrees to either side
- The eyes should remain fixated on your nose
- In a positive test, the eyes turn with the head, then refixate back to your nose
- You may have to make a number of smaller head movements first to get the patient to relax before doing a more rapid movement
The direction of the arrows indicates the horizontal direction of the fast phase of the nystagmus (a torsional component is not shown). The thickness of the arrows represents the relative intensity of the nystagmus. Panel A shows findings typical of peripheral nystagmus, which remains in the same direction when the direction of gaze changes, and central nystagmus, which changes direction when the direction of gaze changes. Removal of visual fixation increases the intensity of peripheral nystagmus but not of central nystagmus. Panel B illustrates how removal of fixation helps to differentiate peripheral from central nystagmus when the nystagmus is predominantly in one direction of gaze during fixation. With removal of fixation, peripheral nystagmus may increase in intensity and become apparent in more than one direction of gaze. Techniques to remove fixation include using an ophthalmoscope (the fundus moves opposite the nystagmus) or looking at the eye movements through the closed eyelids.)
Central Vertigo can also be caused by Drugs

^a Typical examples include phenytoin, carbamazepine, and phenobarbital.
Cover Test for Skew deviation

Vertical misalignment of the eyes may be obvious. But more subtle abnormalities can be appreciated by having the patient fixate on a target across the room, then covering each eye in an alternating fashion looking for a vertical refixation when the cover is shifted.
